Chapter 2 problems
Problem 2.1
(a) The Sun has a surface temperature of 5800 K and an average radius $6.96 \times 10^8$ m. Assuming the mean Sun-Mars distance is $2.28 \times 10^{11}$ m, what is the total radiative power per unit area incident on the upper Mars atmosphere facing the Sun?

(b) If the surface temperature of the Sun was 6800 K, by how much would the total radiative power per unit area incident on Mars increase?

Problem 2.2
(a) A positron has charge $+e$ and the same mass $m_0$ as a bare electron. The energy of a particle with rest mass $m_0$ moving at velocity $v$ with momentum $p = \gamma_{\text{Lorentz}} m_0 v$ is $E = \gamma_{\text{Lorentz}} m_0 c^2$ where $c$ is the speed of light and $\gamma_{\text{Lorentz}}$ is the Lorentz factor such that $\gamma_{\text{Lorentz}}^2 = \frac{c^2}{c^2 - v^2}$. Why does a single high-energy photon not decay into an electron and a positron?

(b) Experiments show that two colliding real photons $\gamma_1$ and $\gamma_2$ can create particles that have mass (D. L. Burke et al. Phys. Rev. Lett. 79, 1626 (1997)). Describe the conditions in which these photons decay into a positron and an electron.

Problem 2.3
Consider a lithium atom (Li) with two electrons missing.

(a) Draw an energy level diagram for the Li$^{++}$ ion.

(b) Derive the expression for the energy (in eV) and wavelength (in nm) of emitted light from transitions between energy levels.

(c) Calculate the three longest wavelengths (in nm) for transitions terminating at $n = 2$.

(d) If the lithium ion were embedded in a dielectric with relative permittivity $\varepsilon_r = 10$, what would be the expression for the energy (in eV) and wavelength (in nm) of emitted light from transitions between energy levels.

Problem 2.4
A particle mass $m$ moving in a real potential is described by wave function $\psi(x, t)$.

(a) Write down the expression for the average value of the particle position $\langle x \rangle$ and then make use of the Schrödinger equation to show that the average value of momentum is

$$\langle p \rangle = m \frac{d}{dt} \langle x \rangle = \frac{i\hbar}{2} \int_{-\infty}^{\infty} \frac{d}{dx} \left( \hat{\psi} \frac{\partial}{\partial x} \psi - \frac{\partial}{\partial x} \hat{\psi} \psi \right) dx$$

(b) Evaluate the integral in part (a) and show that

$$\langle p \rangle = \int_{-\infty}^{\infty} \psi^* \left( i\hbar \frac{\partial}{\partial x} \right) \psi dx$$

so that one may identify the momentum operator as

$$\hat{p} = -i\hbar \frac{\partial}{\partial x}$$

Problem 2.5
Create a simple model of a heterostructure diode that predicts current increases exponentially with increasing forward voltage bias. Explain the assumptions you make to develop the model. Under
what conditions will this predicted behavior fail? By how much is voltage bias across an ideal diode increased to change current by a factor of 10 at room temperature \((T = 300 \text{ K})\)? Does this represent a fundamental limit to power dissipation in electronic switching devices operating at room temperature?

**Problem 2.6**

Write down the Hamiltonian operator for (a) a one-dimensional simple harmonic oscillator, (b) a helium atom, (c) a hydrogen molecule, (d) a molecule with \(n_n\) nuclei and \(n_e\) electrons.

**Problem 2.7**

Calculate the classical velocity of the electron in the \(n\)-th orbit of a \(\text{Li}^{++}\) ion. If this electron is described as a wave packet and its position is known to an accuracy of \(\Delta x = 1 \text{ pm}\), calculate the characteristic time \(\Delta t_{\Delta x}\) for the width of the wave packet to double. Compare \(\Delta t_{\Delta x}\) with the time to complete one classical orbit. Should the electron be described as a particle or a wave?

**Problem 2.8**

What is the Bohr radius for an electron with effective electron mass \(m^* = 0.021 \times m_0\) in a medium with low-frequency relative permittivity \(\varepsilon_r = 14.55\) corresponding to the conduction band properties of single crystal InAs? What is the effective Rydberg energy for an electron describing a hydrogenic orbit in the medium?

**Problem 2.9**

Because electromagnetic radiation possesses momentum it can exert a force. If completely absorbed by matter, the absorbed electromagnetic radiation energy per unit time per unit area is a pressure called radiation pressure.

(a) If the maximum radiative power per unit area incident on the upper Earth atmosphere facing the Sun is 1.4 kW m\(^{-2}\), what is the corresponding radiation pressure?

(b) Estimate the photon flux needed to create the pressure in (a).

(c) Compare the result in (a) with the pressure due to one atmosphere.

(d) Assuming Poisson statistics applies to part (b), what is the fluctuation in pressure per unit time?

**Problem 2.10**

(a) As described in Chapter 2, Alice can transmit information to Bob via a quantum communication channel that uses single photons and nonorthogonal polarization states. Explain Bob’s choice of test basis in Fig. 2.8.

(b) In the absence of a single photon source, optical quantum key distribution (QKD) uses light from an attenuated laser. In a particular system the mean photon number per pulse is 0.1 and the probability of single photon emission is 0.09. The link operates with a clock rate of 1.25 GHz (bit time \(\tau = 800 \text{ ps}\)), average optical loss in the link is -10 dB, and time jitter in the photodetector requires two bit-time intervals be used for photon detection. What is the maximum sustained data rate for guaranteed secure QKD in the system?

(c) No light can pass between two linear polarizers if their respective polarizations are oriented at \(90^\circ\) to each other. If a third linear polarizer oriented at a \(45^\circ\) angle is placed between the two lin-
ear polarizers, what is the maximum fraction of incident light intensity that can pass through the system?

Problem 2.11
A particle mass $m$ moving in a real potential is described by wave function $\psi(x, t)$ and Schrödinger’s equation. Show that

$$\frac{d}{dt} \int_{-\infty}^{\infty} |\psi(x, t)|^2 dx = 0$$

so that if the wave function $\psi(x, t)$ is normalized it remains so for all time.

Problem 2.12
Fixed positive charge is uniformly distributed in the volume of a sphere radius $R$ with charge density $\rho = e \times 1.5 \times 10^{28} \text{ m}^{-3}$.

(a) Calculate the force on an electron point-particle initially placed at the surface of the sphere.
(b) Assuming the electron in (a) is free to move in the volume of the sphere, what is the potential seen by the electron and what is its subsequent motion?
(c) What energy and wavelength of photons do you anticipate being absorbed by the system?
(d) At what radius $R_e$ does your model predict the velocity of the electron exceeds the speed of light in vacuum?
(e) If the total system consisting of the sphere of positive charge density and the electron is charge neutral what is the value of the radius, $R$? How does electron dispersion limit the validity of your model?

Problem 2.13
Identical spherical atoms of unit density are arranged in space so that the nearest neighbor atoms just touch. Show that such a close-packed arrangement results in density (or “packing fraction”) for the indicated cubic lattices:

<table>
<thead>
<tr>
<th>Structure</th>
<th>Density</th>
</tr>
</thead>
<tbody>
<tr>
<td>Diamond</td>
<td>$\frac{3}{16} \pi = 0.34$</td>
</tr>
<tr>
<td>Simple cubic (SC)</td>
<td>$\frac{8}{6} = 0.52$</td>
</tr>
<tr>
<td>Body-center cubic (BCC)</td>
<td>$\frac{\sqrt{2} \pi}{8} = 0.68$</td>
</tr>
<tr>
<td>Face-center cubic (FCC)</td>
<td>$\frac{\sqrt{2} \pi}{6} = 0.74$</td>
</tr>
</tbody>
</table>

Problem 2.14
The intensity of two co-propagating electromagnetic waves with identical frequency $f_0$, polarization, and wavelength $\lambda_0$ depends on their phase difference.

(a) Write a MATLAB program that reproduces Fig. 2.2 using two waves of frequency $f_0 = 200 \text{ THz}$. Plot the normalized electric field intensity versus phase delay. Consider phase delays up to $\pm 4\lambda_0$.
(b) Modify your code from part (a) so that each wave consists of two equal amplitude component waves, one with frequency $f_1 = 220$ THz and the other with frequency $f_2 = 180$ THz. Plot the normalized field intensity versus phase delay. Consider phase delays up to $\pm 8\lambda_0$.

(c) Modify your code from part (b) so that the component wave amplitude has a Gaussian distribution as a function of frequency. The Gaussian distribution has a standard deviation of 20 THz about the center frequency, $f_0 = 200$ THz. Plot the normalized field intensity versus phase delay for up to $8\lambda_0$ when each wave consists of 3, 4, 5, and 10 component frequencies evenly spaced between $\pm 3$ standard deviations. What is the field intensity at a delay length of $8\lambda_0$ when 10 component frequencies are included in the calculation? Explain the reason for this value.

Include a printout of your final code from part (c) as well as the generated plots with your assignment.

Problem 2.15
The wave function at time $t = 0$ for an electron localized as a Gaussian wave packet in one-dimension centered at $x = x_0$ and having spatial width $\Delta x$ and momentum $\hbar k_0$ is

$$\psi(x, t = 0) = \sqrt{\frac{1}{\pi \Delta x}} e^{i k_0 x - \frac{(x - x_0)^2}{4 \Delta x^2}}.$$

(a) Find the wave function normalization constant $A$ and show that $\langle x \rangle = x_0$ and $\sqrt{\langle x^2 \rangle - \langle x \rangle^2} = \Delta x$.

(b) Take the Fourier transform of $\psi(x, t = 0)$ to determine $\psi(k, t = 0)$. Making the substitution $\Delta k = (2\Delta x)^{-1}$, compare your result to that of part (a). Explain the significance of $\Delta k \Delta x = 1/2$.

Hint: You may use Cauchy’s integral theorem, which states that $\int f(z) \, dz = 0$ where $z$ is a complex variable and $f(z)$ has no poles within the closed integration loop.

(c) Find $\psi(x, t = 0)$ and $\psi(k, t = 0)$ in the limit $\Delta x \to 0$ and describe how the electron wave packet evolves with time. If we were to measure the electron’s location with absolute certainty at time $t = 0$, where can we expect to locate the electron at any subsequent time? Explain your result.

(d) If a localized single photon in free-space can be described by the same initial Gaussian wave packet $\psi(x, t = 0)$, how will it evolve in time? Explain the difference in the predicted behavior of the photon compared to the electron.

Problem 2.16
Optical quantum key distribution (QKD) protocol may be viewed as a sensor capable of detecting eavesdropping on an optic link. Alice and Bob use the B92 protocol and measure error rate to detect the presence of Eve, an eavesdropper, in an otherwise lossless optical QKD link.

(a) What is the average error ratio generated by eavesdropping?

(b) What can Alice and Bob infer about the methods used by Eve?

Problem 2.17
The normalized first-order time-independent correlation function of a classical electric field $E(t)$ is

$$g^{(1)}(\tau) = \frac{\langle E(t)E(t + \tau) \rangle}{\langle E^2(t) \rangle},$$

where the brackets $\langle \rangle$ indicate an average over all time, $t$.

(a) Show that $g^{(1)}(\tau) = g^{(1)}(-\tau)^*$, $|g^{(1)}(\tau)| \leq 1$, and that light of single frequency $\omega_0$ has $g^{(1)}(\tau) = e^{-i\omega_0 \tau}$. 

Applied quantum mechanics
(b) The probability there are \( n \) photons in a single radiation mode of a cavity with frequency \( \omega \) is given by Boltzmann's law

\[
P_n(n) = \frac{e^{-E_n/k_B T}}{\sum_{n=0}^{\infty} e^{-E_n/k_B T}}
\]

where the quantized energy of a photon is \( E_n = (n + 1/2)\hbar \omega \). Show that \( P_n(n) \) may be written as

\[
P_n(n) = (1 - e^{-\hbar \omega /k_B T}) e^{-\hbar \omega /k_B T} - e^{-(n+1/2)\hbar \omega /k_B T} - 1
\]

and that the mean photon number is \( \bar{n} = 1/(e^{\hbar \omega /k_B T} - 1) \). Show that \( P_n(n) \) may be written as

\[
P_n(n) = e^{-\hbar \omega /k_B T} \frac{\bar{n}^n}{n!}
\]

(c) The second-order time-independent correlation function of classical electric field intensity

\[
I(t) = E(t)E(t)
\]

with a stationary statistical distribution is

\[
g^{(2)}(\tau) = \frac{\langle I(t)I(t+\tau)\rangle}{\langle I(t)\rangle \langle I(t)\rangle}
\]

Show that \( g^{(2)}(\tau) = g^{(2)}(-\tau) \), \( g^{(2)}(0) \geq 0 \), \( g^{(2)}(0) \geq 1 \), and \( g^{(2)}(0) \geq g^{(2)}(\tau) \).

(d) Calculate \( g^{(2)}(\tau) = 0 \) for a monochromatic wave with sinusoidal intensity modulation of the form \( I(t) = I_0(1 + A \sin(\omega_0 t)) \), where \( |A| \leq 1 \) and \( I_0 \) and \( \omega_0 \) are constant.

(e) Simulate the electric field \( E(t) \) of thermal light by using MATLAB to generate and plot an array of at least 100,000 random Gaussian numbers with unit standard deviation and mean of zero. Write a program to spectrally filter \( E(t) \) by convolving with a Gaussian function of standard deviation \( \tau_C = 50 \) data points to obtain \( E_{\text{Filter}}(t) \). Calculate and plot the intensity for 2000 data points along with a probability histogram of intensity for both \( E(t) \) and \( E_{\text{Filter}}(t) \). Verify for both cases that the histogram follows the thermal distribution given by \( P(I) = \frac{1}{I_0^2} e^{-I/I_0} \). Plot \( g^{(1)}(\tau) \) and \( g^{(2)}(\tau) \) using \( E_{\text{Filter}}(t) \) for time-delay interval range \( \pm 500 \) data points. Verify \( g^{(2)}(\tau) = 1 + [g^{(1)}(\tau)]^2 \) and that \( g^{(1)}(\tau) \) is of the form \( e^{-(\tau/\tau_C)^2} \). Explain your results.

**Problem 2.18**

In quantum mechanics the \( \pm \hbar /2 \) spin of an electron charge \( e \) and mass \( m_0 \) emerges as a consequence of rotational symmetry and a relativistic treatment of the Schrödinger equation.

(a) Suppose spin were a classical concept due to the rotation of a spherical electron of classical radius \( r_e = \frac{e^2}{4\pi e_0 m_0 c^2} \) about an axis passing through its center. Assuming a uniform classical electron density in the sphere, explicitly find the moment of inertia of such an electron.

(b) If the angular momentum of the classical electron is \( \hbar /2 \) what is the speed of the surface of the electron at its equator? Compare this to the speed of light, \( c \), and comment on what you have learned.

(c) If all the electron density is in a thin torus of vanishingly small cross-section making a ring at the equator calculate the radius at which the ring speed is 1% of \( c \). Calculate the current in the ring and the magnetic field through the ring.

(d) Calculate the magnitude and direction of the classical force due to the coulomb interaction experienced by the electron charge density of the ring in (c).

(e) What happens to the force you calculated in (d) if, as in quantum mechanics, the electron is a point particle?
Problem 2.19
As illustrated in the following figure, we start by assuming it is possible to model one aspect of the photoelectric effect as a single photon of energy $h\omega$ colliding with an electron mass $m_0$ with initial energy $E$ and momentum $\hbar k$ whose trajectory is normal to that of the photon. After the collision the final momentum of the electron makes angle $\theta$ with its initial momentum.

(a) Suppose it is possible to transfer all the initial momentum of the photon to the electron. Use momentum conservation to find electron scattering angle, $\theta$, as a function of photon energy, $h\omega$, and, if initial electron energy is $E = 1 \text{ eV}$ and $\theta = \pi/4$, what is the value of photon energy, $h\omega$?

(b) Explain why the scenario in (a) is not physical and how you would develop a correct model of the photoelectric effect.
